Scope of BM.

Looks for improvement and longivity via the recognition of disease of lifestyle.

The clinical application range from areas where therapist control of environment contigencies. behavioral pediatrics and pain management.

Two To areas emphasising self management procedure, weight & smoking management

Major themes of BM :-

1. Management of behaviour which in itself constitutes a problem for example sexual dysfunction.
2. Management of the behaviour of a health care provider for ex malpractice behaviour
3. Adherence to treatment regimenes. Force The injection of hypetension medication.
4. Management of health related behaviour for prevention of disease like smoking.

Behavior and Psychological influence on health.

Three general pathways through which behavioral & psychological factors may influence the etiology, progression, treatment or prevention of disease.

1. Direct effect of cognitive emotion and behavioral process on body symptoms for eg nerves, immune or endocrine system.

2. Health enhancing behavior, health impairing behaviours.

3. Responses to perceived or actual illness.

Behavioural influence in disease process:-

Research on biological correlates of psychological have shown that nerves, immune and endocrine systems interact in a reciprocal fashion and regulate a variety of states and condition.

The biological stress in particular have been a focus of a lot of research.

Theories of Health Behaviour:-

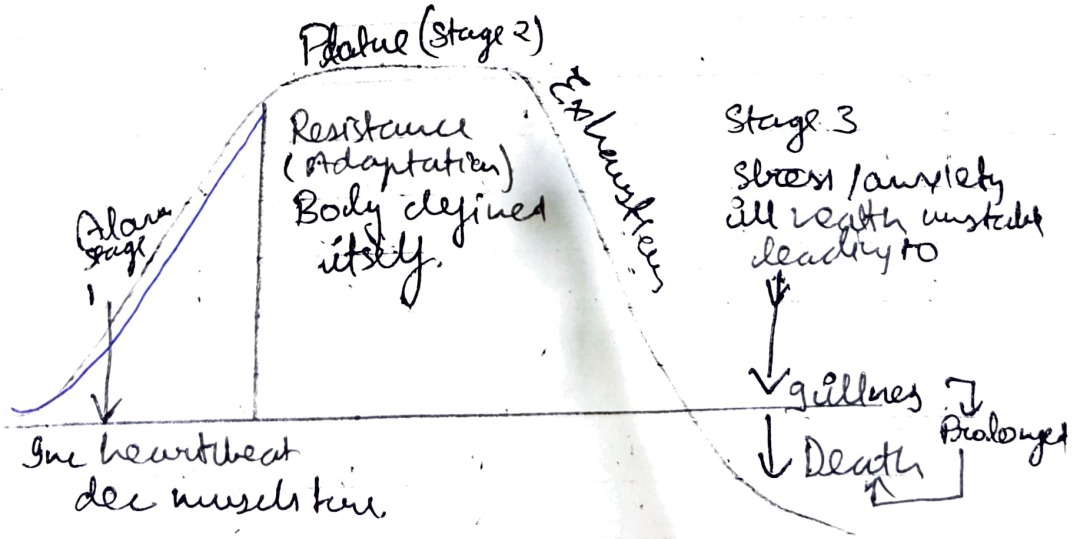

Attribution theory - (Tailor et. al 1984)

Health Locus of control (Wallston & Walston 1984)

Unrealistic optimism (Weinstein 1984)
Transtheoretical model of change
Heath belief model. (Norman and Conner 1994)
Protection motivation theory
Social cognition model.
Theory of planned behavior.
The health action process approach

Psychological model of disease

Hans Selye (General adaptation Syndrome) (1936) model of stress.

Was introduced first in 1936. According to Hans Selye he gave the concept of non specific response of the body to any demand to any

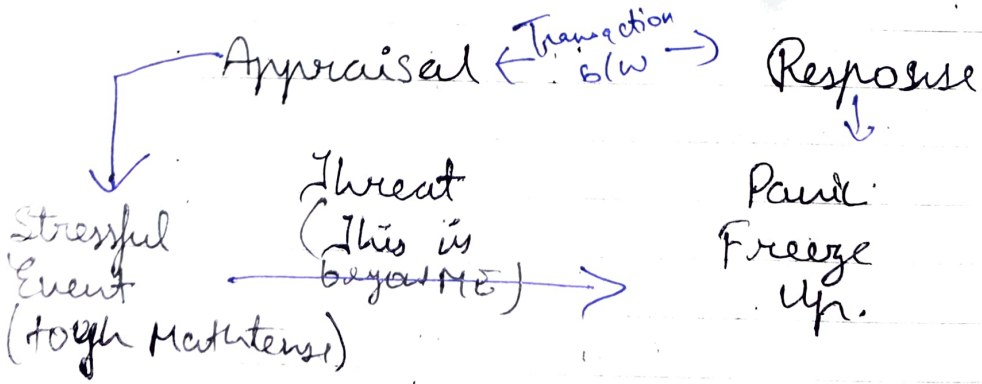

Stressors.

Stage 1 Alarm stage, bodily changes occur. there are 2 type of stress acute stress and chronic stress. In this stage there can be acute stress present.

Stage 2 Ressistance stage. In this stage body starts defending itself. i body start adapt to need and starts changing.

Stage 3 Exhaustion stage. Body has given up. ill health and it unstablity & leading to illness. If the stress is not eliminated than it can lead to death.

Transactional Model :-

Challenge → Aroused.
(I have got the Focused apply, all I know)

Richar Lazarus gave the transactional model of coping.

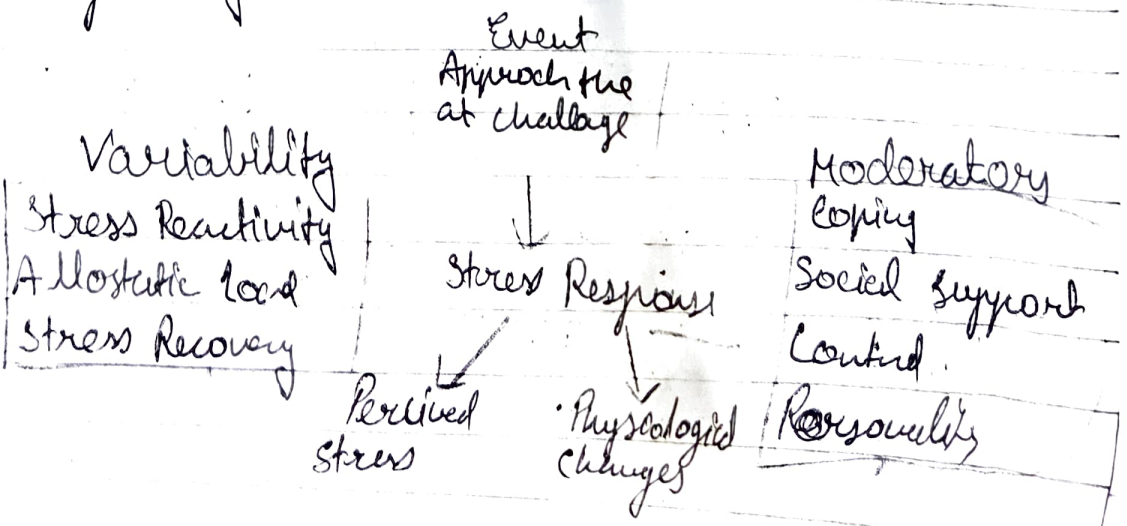

How do you understand and react to a particular situation determines your response.

Between environment and stressors.

Imbalance between the demand and resources. When the demand inc and excessed to reduce stress then we have to control our demands.

The interpretation of the stressful event as more stressed than it actually is the event.

The interaction b/w psychological & physiological aspect of stress.

What is allostasis ?

The active process of maintaining or restablish homeostasis

Homeostasis are those aspect of physiology (PH) that maintain life.

Allostasis refers to the ability of the body to produce harmones (like cortisol, epinephrin and other mediater like cytokines that help an animal adapt to a new situation or change.

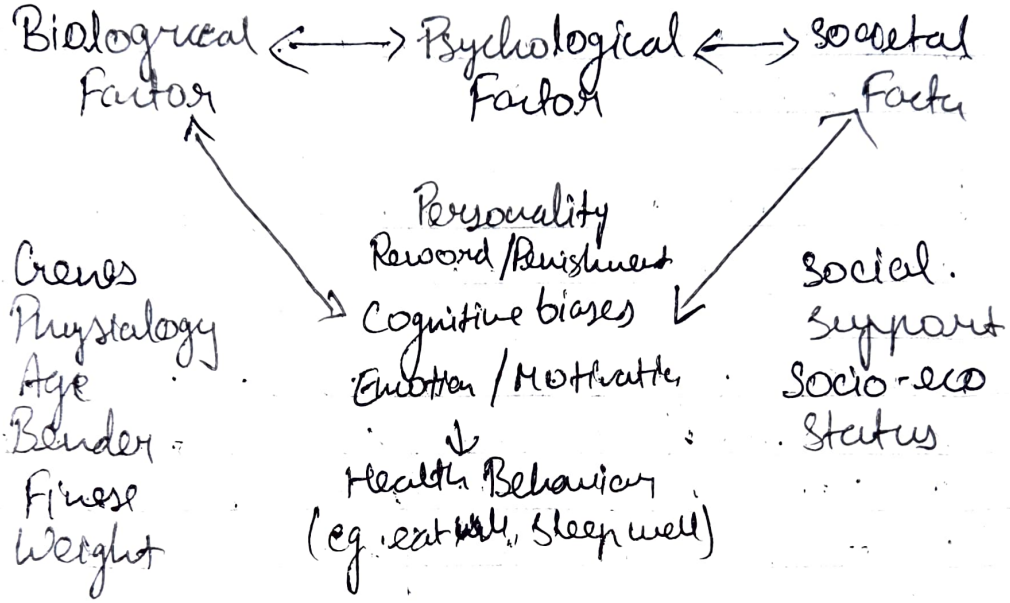

Allostatic state refers to elevated level of allostatic mediator.

Allostatic load cumulative change due to allostatic mediators

Allostatic overload weare and tear pathophysic from prolonged allostatic load. For eg:- atherosclerosis, neural damage and cell loss.

Health Behavior.

demand can cause stress.

Model of understanding Illness

Social Cognition Models
- Normative Belief
- Parental Influence

- Self efficacy (I can stop smoking if I want to)
- The concept of incentives (Behaviour is governed by the consequences)

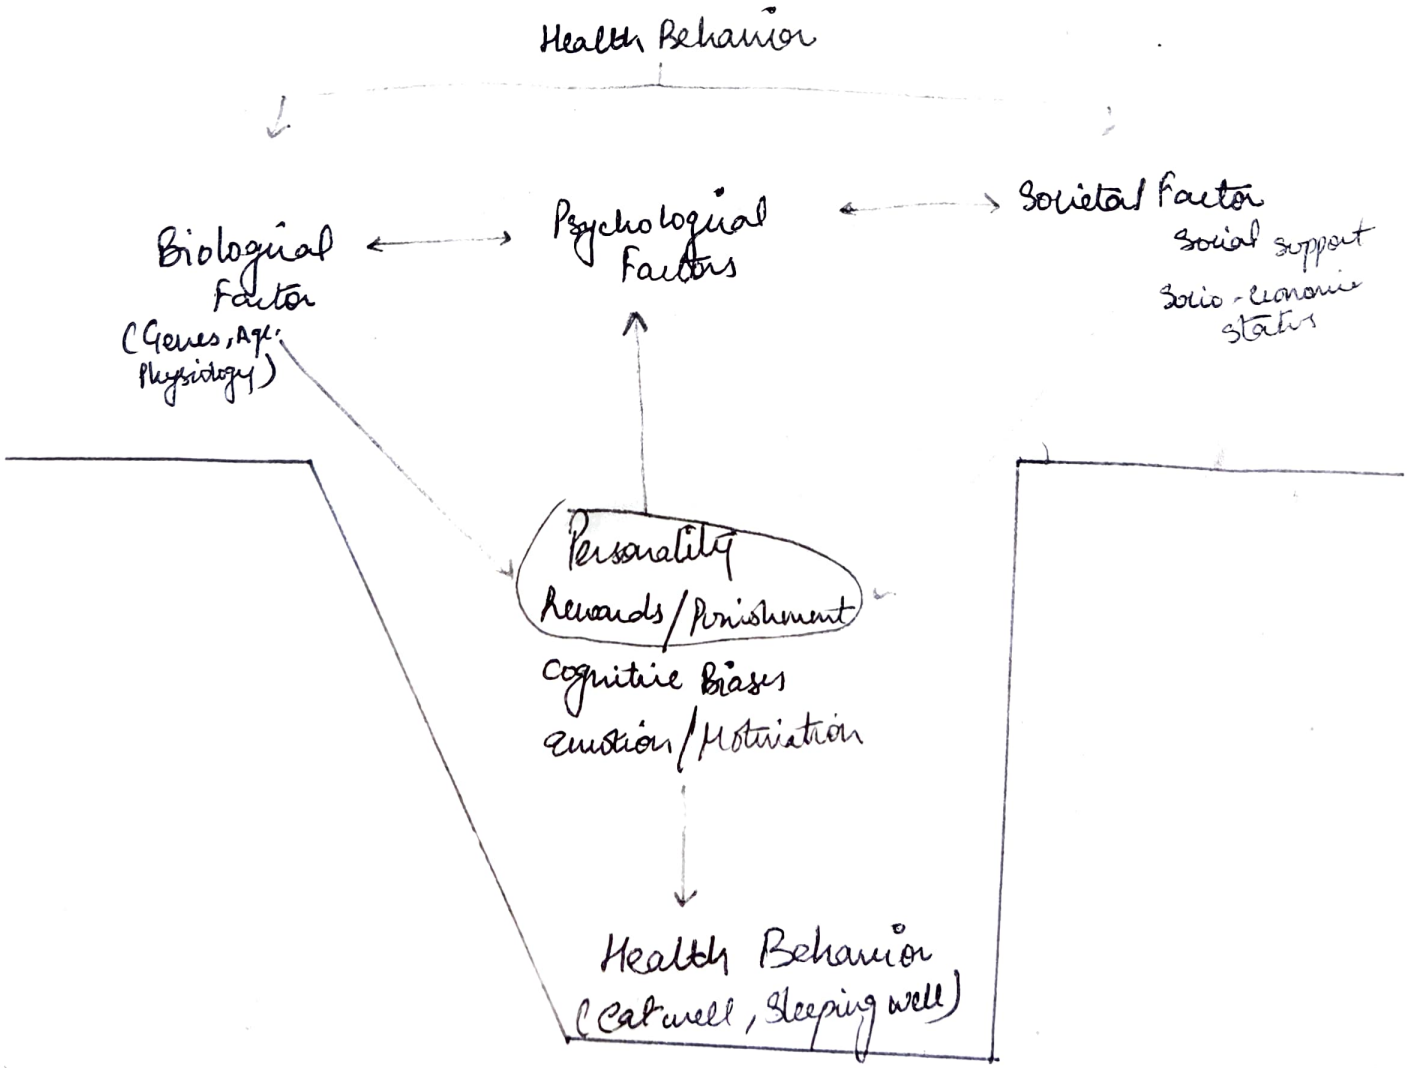

demand can cause stress.

(6) Protection Motivation theory (Rogers 1985)
(7) Theory of planned behaviour
(8) Social cognition model
(9) The health action process approach

Psycho Pysiological model of Disease

Hans Selye's (General Adaptation Syndrome) GAS

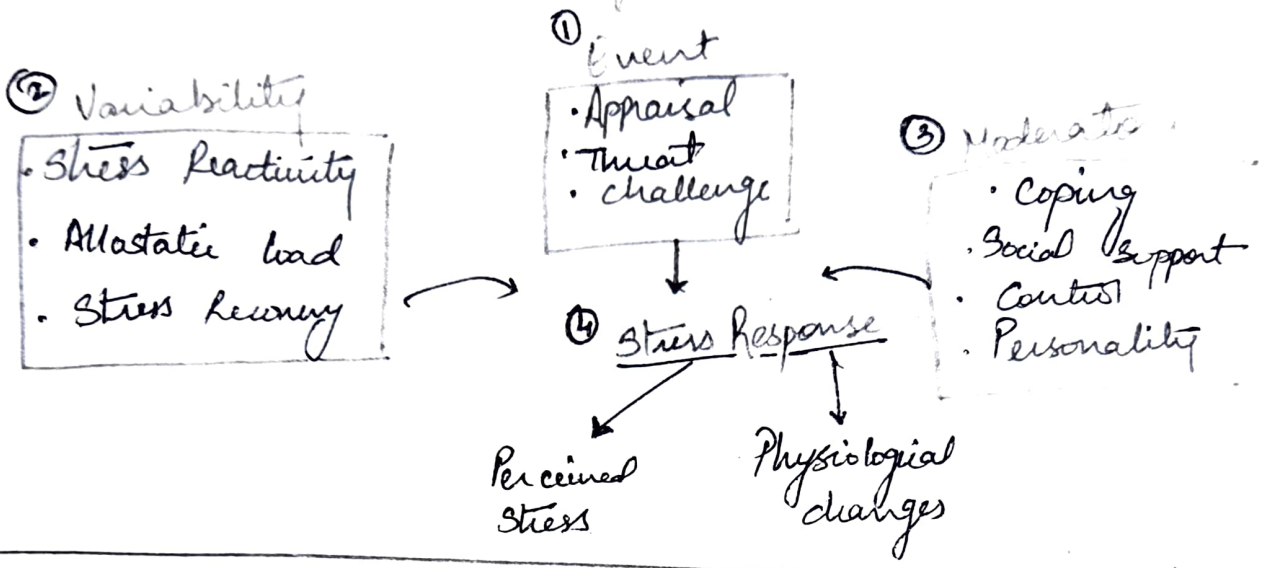

Health Behaviour Model

The Interaction b/w psychological & physiological

Allostasis : the active process of maintaining / re-establishing body's Homeostasis.

↳ Homeostasis : are those aspect of physiology (pH balance, oxygen balance) that maintain life

Allostasis refers to the ability of the body to produce hormones (like cortisol, epinephrine) & other mediators (like cytokine) that help an animal adapt to a new situation or challenge.

Allostatic State : Elevated levels of allostatic mediators

Allostatic load : cummalative change due to allostatic mediators

Allostatic overload : wear and tear pathophysiology from prolonged allostatic load for eg- atherosclerosis, neural damage & cell loss.
